#LHCnext20y

School of Physics & Astronomy Public Lecture

2nd March 2016

University of London

Queen Mary

Standard Model describes 3 of the 4 fundamental forces of nature with unprecedented accuracy electromagnetic force / weak nuclear force / strong nuclear force

The Next 20 Years of the LHC - QMUL Public Lecture - 2nd March 2016

(what universe would look like with no Higgs boson)

The Higgs Boson

Higgs also saves the SM from some embarrassing predictions Examine theoretically predicted energy dependence of scattering process $e^+e^- \rightarrow W^+W^-$

Processes (a) (b) and (c) become larger than total e⁺e⁻ reaction rate! (probability greater than 100%)

Higgs-like particle is needed to cancel $e^+e^- \rightarrow W^+W^-$ theoretical inconsistency

Requires Standard Model Higgs to be <~1TeV

If Standard Model is correct we will find the Higgs at the LHC!

If Standard Model is wrong some new particle must do this job

win-win situation!

The Large Hadron Collider

27 km circumference tunnel in France / Switzerland - near Geneva Highest energy accelerator in the world Protons accelerated to 6,500 GeV = 99.9999991% speed of light High vacuum Super cold superconducting magnets to achieve strong magnetic fields 17,000 A current in magnets Four experiments: Atlas CMS

LHCb

Alice

The ATLAS experiment at the LHC 3500 physicists 174 universities 38 countries 7000 tonnes Mass of the Eiffel Tower Half the size of Notre Dame data rate: 20,000,000 Gb/s

Particle Signatures

Large experiments needed to measure outgoing particles from collisions Experiment consists of layered detectors each sensitive to different types of particle Look for signatures of particle types

Eram Rizvi

High energy collisions equivalent to temperatures 100,000 times hotter than sun's core High vacuum needed to avoid unwanted collisions with air molecules - less dense than solar system 1200 dipole magnets to bend the protons Protons circulate 11,000 times per second Generates up to 600 million collisions per second

LHC costs for material, construction, personnel (excluding experiments) = € 3, 000,000,000

The Next 20 Years of the LHC - QMUL Public Lecture - 2nd March 2016

Why collide protons in LHC? easy to produce easy to accelerate (compared to electrons) are composite - bags of fundamental quarks and gluons

In reality the LHC is a quark / gluon collider

Feynmar	n diagram pieces
\longrightarrow	fermion (quark or lepton)
	boson (W, Z, photon)

- 00000 gluon
 - ----- Higgs boson
 - vertex: coupling of boson to fermion
 = strength of interaction α

We measure reaction rates for different collision processes between quarks / gluons

Many different types of process occur

Compare measurement to precipions using Feynman diagrams

Momentum is transferred from quark pair to muon pair \Rightarrow Z has transmitted a force!

Feynman Diagram is an equation Allows calculation of reaction rate

More complicated loop diagrams also contribute \rightarrow quantum fluctuations

Complex diagrams have more vertices \rightarrow smaller contributions

Examples of processes / Feynman diagrams measured at the LHC and compared to theory calculations Approximately ordered in decreasing reaction rate (see next page)

The Next 20 Years of the LHC - QMUL Public Lecture - 2nd March 2016

Standard Model Production Cross Section Measurements

Status: Nov 2015

Standard Model Production Cross Section Measurements

Ratio of measurement to prediction Everything is consistent with unity

> → Data and theory agree! (within their uncertainties)

ATLAS Preliminary
Run 1,2
$$\sqrt{s} = 7, 8, 13$$
 TeV

I personally was involved in some of these measurements with my PhD students

Higgs Hunting

clear peak, low background, but low rate too

subtle 'bump' on top of large background

small excess, large background, high rate

Higgs Hunting: Properties of the Higgs

Is the Higgs coupling to particles \propto mass?

Coupling strength of Higgs to particle ATLAS and CMS LHC Run 1 Preliminary Observed 10⁻¹ SM Higgs boson 10⁻² 10⁻³ 10^{-4} 10⁻¹ 10² 10 Particle mass [GeV] Is the Higgs being produced at the expected rate?

The Higgs particle is being produced at about the predicted Standard Model rate

Have we found it ? yes! We still need to measure all of it's properties Are there more Higgs-like particles ? Any signs of new physics??

The Standard Model

The Next 20 Years of the LHC - QMUL Public Lecture - 2nd March 2016

The Standard Model works beautifully! Describes all experimental data!

But it's incomplete Many things have to be inserted by hand Leaves many questions unanswered

A good theory has few parameters to explain many phenomena e.g. Newtonian gravity has 1 parameter *G* to describe all planetary motions!

$$F = G \frac{m_1 m_2}{r^2}$$

The Standard Model has 22 parameters to be measured:

6 quark masses

3 charged leptons masses

3 couplings α_1 , α_2 , α_3 for 3 forces

4 quark mixing parameters

4 neutrino mixing parameters

1 weak boson mass (1 predicted from other EW params)

1 Higgs mass

We feel this is too much for a fundamental theory (but better than 105 params of supersymmetry)

We have no idea what 96% of the universe is! unknown form of dark energy (74% of universe's mass!) unknown form of dark matter (22% of universe's mass!)

Two gas clouds collide Clouds slow down Dark matter passes through

No treatment of gravity in the Standard Model... In a symmetric theory gauge bosons are massless Higgs mechanism explains EW symmetry breaking \rightarrow EW bosons acquire mass

...but there must be a deeper relationship between Higgs / mass / gravity / dark energy

We know quantum gravity effects must play a role at the Planck scale i.e. energy $\sim 10^{19} \, \text{GeV}$

2<u>0</u>

Standard Model is lacking: why 3 generations of particles? why do particles have the masses they do? no consideration of gravity on quantum level...

In the Standard Model matter and anti-matter produced in equal quantities In the Big Bang: for every quark, one anti-quark is also produced As universe cools expect all particles and anti-particles to annihilate ⇒ soon after big bang all matter will have annihilated to photons

We should not exist!

For every proton/neutron/electron in universe there are 10⁹ photons (CMB - cosmic microwave background) Thus matter/anti-matter asymmetry must be 1:10⁹ We cannot see where this asymmetry lies...

(Actually SM can account for only 1000th of this asymmetry)

e⁺ e⁻ annihilation

The Hierarchy Problem

to maintain ~ 100 GeV Higgs mass

Every Standard Model particle gets a supersymmetric partner sparticle with opposite spin

None of these has been observed

105 new parameters required by theory - So why bother??

Eram Rizvi

Astronomers observations show Dark Matter is:

- probably a particle
- electrically neutral (does not interact with photons)
- cold (non-relativistic)
- stable (does not decay to anything else)
- weakly interacting (else galaxies won't form)
- cannot be neutrons (they're unstable)
- cannot be neutrinos (mass too small)

In LHC pp collision SUSY sparticles could be produced In some models only sparticle & anti-sparticle pairs can be formed This means the lightest neutralino cannot decay into ordinary SM particle It is stable!

This Lightest Supersymmetric Particle (LSP) could be Dark Matter!

In this case gluino pair is created Each decays to two quarks, W and a stable neutralino Search for this experimental signature in ATLAS

Eram Rizvi

Hierarchy Problem

Why is Higgs mass (~1 TeV) so much smaller than the Planck scale (10¹⁹ GeV)? Such calculations need to take account virtual fluctuations

Higgs interacts with all spin ½ particle-antiparticle pairs in the vacuum

Higgs mass quantum corrections diverge up to 10¹⁹ GeV

If SM valid up to Planck scale then incredible fine-tuning of cancellations is needed to ensure ~1 TeV Higgs mass

Seems unnatural

Only a problem for the Higgs (only SM particle with spin 0)

New SUSY sparticles (e.g. stop squark) contribute and cancel identically

Higgs interaction with spin 0 sparticle cancels SM quantum corrections above

GUT Unification

Another of SUSY's charms:

Three force couplings extrapolated to Planck scale do not intersect

- Naturally extends to quantum gravity
- Provides a candidate for dark matter
- SUSY solves hierarchy problem
- Brings about GUT unification of couplings
- Some general assumptions can reduce 105 parameters to 5

What are GUTs?

Grand unified theories: electroweak + QCD TOE = Theory of everything = GUT + quantum gravity

Occurs at energy scales when couplings reach strength of gravity

Construct a quantity with dimensions of energy or length from constants of relativity, quantum mechanics & gravity: c, \hbar , G

Quantity	Symbol	unit
speed of light	С	m s⁻¹
Gravitational constant	G	m ³ Kg ⁻¹ s ⁻²
Planck constant	ħ	Kg m⁻² s⁻¹

$$E_{\text{Planck}} = \sqrt{\frac{\hbar c}{G}} = 10^{19} \text{ GeV} \qquad L_{\text{Planck}} = \sqrt{\frac{\hbar G}{c^3}} = 10^{-35} \text{ m} \qquad T_{\text{Planck}} = \sqrt{\frac{\hbar G}{c^5}} = 10^{-44} \text{ s}$$
Planck energy Planck length Planck time

This exercise very roughly tells us what energy or length scale we need to see effects of quantum gravity

These are all equivalent: experiments probing the Planck energy, also probe distances of Planck length

 10^{19} GeV = 10,000,000,000,000,000 GeV No chance to build a collider at this energy!

Extra spatial dimensions of size < 1 mm could exist gravity has only been tested down to this scale!

Where are the extra dimensions? curled up (compactified) and finite only visible at small scales / high energies

With extra dimensions gravity becomes modified New

With *n* extra spatial dimensions each of size *R* then $F = G_D \frac{m_1 m_2}{r^{2+n}}$

Newton's law:
$$F = G \frac{m_1 m_2}{r^2}$$

i.e

Force F between two masses m_1 and m_2 distance r apart G is Gravitational constant

 G_D is higher dimensional Gravitational constant

$$F = \left(\frac{G_D}{R^n}\right) \frac{m_1 m_2}{r^2}$$

$$G = \frac{G_D}{R^n}$$

For *r* much larger than *R* we recover Newtonian gravity

dilution due to volume of extra dimensions

In extra dimensions full scale of gravity M_D is given by

Planck scale: $M_P^2 = \frac{\hbar c}{G}$

$$M_D^2 = \frac{\hbar c}{G_D} = \frac{M_P^2}{R^n}$$

Thus M_D can be ~ 1 TeV when R^n is large

LHC could open the possibility of creating mini-black holes & gravitons laboratory for testing quantum gravity!!!

Effect of increasing the collision energy from 8 TeV to 13 TeV

factor 2 increase in production rate for new particle with mass $M_X = 0.1 \text{ TeV}$ factor 10 increase in production rate for new particle with mass $M_X = 2 \text{ TeV}$ factor 100 increase in production rate for new particle with mass $M_X = 4 \text{ TeV}$

15th December 2015 ATLAS released first tranche of new results using run 2 data

What are we looking for ?

MUR

What are we looking for ?

NUA

Large increases in intensity

Requires significant changes to LHC magnets Higher intensity means faster degradation of experiments

LHC High Luminosity Upgrade

In 2023 LHC will shutdown for 2 years Upgrade machine / magnets to provide more data (luminosity) Magnets accelerate, bend and focus the beams

New high performance superconducting magnets needed all around LHC ring Magnetic field $8T \rightarrow 12 T$

Upgrade cryogenics systems to keep magnets cold

without

Crab cavities

ATLAS High Luminosity Upgrade

ATLAS detector in Run-2

Current LHC operation yields typically 23 overlapping collisions every 25ns

Large flux of particles in 10 years of operation causes damage to detector

example: silicon wafer crystal structure is deformed and electrical properties degraded

ATLAS detector in High Luminosity run

Future LHC operation will yield typically 200 overlapping collisions every 25ns !!!

ATLAS will entirely replace inner tracker in 2023

Upgrade 'trigger electronics' to select interesting collision events online to record to disk for offline analysis

Queen Mary group strongly involved in both efforts

- Run 2 restarts in April expect 100 fb⁻¹ by 2018 (five times more data than now)
- By 2023 we will have 300 fb⁻¹ allows us to search for rarer processes
- Many new physics models still to be tested
- Experimental data is the final arbiter of truth!
- Some models appear contrived....
- ... but nature is weird (who could have predicted quantum mechanics?)
- Nevertheless, we should continue to look because we can!
- The 'holy grail' of quantum gravity may be experimentally within reach
- Plenty more work to be done

The Game is On!

The Standard Model- Quarks & Leptons

	quark	symbol	mass MeV/c ²	electric charge	⊭ weak charge	colour charge	spin	all three quantum forces: - electromagnetism - weak force
•	down	d	2	-1/3	yes	yes	1/2	Strong force
Inc	up	u	5	+2⁄3	yes	yes	1/2	
	strange	S	100	-1/3	yes	yes	1/2	
	charm	с	1300	+2⁄3	yes	yes	1/2	all matter particle (quark
۲na	bottom	b	4300	-1/3	yes	yes	1/2	and leptons) have spin 1/2
-	top	t	173000	+2⁄3	yes	yes	1/2	

quarks interact through

lepton	symbol	mass MeV/c ²	electric charge	weak charge	colour charge	spin

leptons interact through one or two quantum forces only:

- weak force
- electromagnetism (not neutrinos)

The values of the weak charge and colour charge are known but not important for our discussion

(4

The Standard Model - Bosons

boson	symbol	mass MeV/c ²	electric charge	weak charge	colour charge	spin	
photon	γ	0	0	no	no	Ι	
W±	W	80400	-1/3	yes	no	Ι	all force carrying
Z	Z	91200	+2⁄3	yes	no	I	particles have spin I
gluons	g	0	0	no	yes	I	
Higgs	h	125000	0	no	no	0	

- photon cannot interact with itself (electric charge = 0)
- W/Z bosons can interact with each other (they have weak charge)
- W bosons can interact with photons (they have electric charge)
- gluons can interact with each other (they have colour charge)
- Aside from mass, the higgs boson has the quantum numbers of the vacuum i.e. all zero!

The Exchange Model

Weak force is responsible for β decay quarks emit heavy W particle which decays

This process is an interaction - it is the expression of a force of nature Newton: force = rate of change of momentum (F=ma)

What can we predict about the exchange particle?

 ΔE is 'used' to produce the particle with mass - what is it? Weak force acts in β decay - has a range of 10⁻³ fm Assume it travels at light speed c - how long does it live for? $c\Delta t = 10^{-3}$ fm & $\Delta E = mc^2$

$$mc^2 \approx \frac{hc}{c\Delta t}$$

So m = $100,000 \text{ MeV/c}^2$ 100 times proton mass!

But we don't understand why W,Z are heavy and photon is massless!

Perturbation theory works but need to calc more diagrams for precision - difficult! For QCD it took 10 years to calculate second order diagrams!

The Higgs Boson - Indirect Effects

Reminder from last week: Quantum fluctuations affect all reaction rate measurements Effects are subtle but measurable Consider e⁻ scattering process:

e.g. Higgs converts into <u>all</u> possible fermion/anti-fermion pairs and back again: $e^+e^-, \mu^+\mu^-, u\bar{u}, s\bar{s}...$

An infinite number of diagrams contribute to this scattering process Result is finite due to cancellations

Precision measurements are weakly sensitive to existence of new particles modifying "loop corrections" Particle masses also affected by such quantum fluctuations Particles have <u>fixed</u> mass, but experimentally measured mass = "bare" mass + quantum loop effects

$$\searrow m_H^2 = m_0^2 + \Delta m_H^2 \checkmark$$

quantum loop fluctuations affect a "bare" particle mass resulting in different but experimentally measurable mass

Englert-Brout-Higgs-Guralnik-Hagen-Kibble Mechanism

Particle with strong Higgs interaction is slowed down Imagine walking with boots on snow Appear to have large mass

Particle with moderate Higgs interaction travels faster Like walking with snow shoes Has moderate mass

Higgs particle appears as a snow-flake

Particle with no Higgs interaction travels at speed of light ⇒ massless particle

Englert-Brout-Higgs-Guralnik-Hagen-Kibble Mechanism

Higgs boson <u>required</u> to explain why W[±] and Z⁰ bosons are very heavy And why the photon is massless

In a symmetric theory all force particles should be massless

In quantum field theory all particles are described as oscillations in a field Electrons are oscillations of the 'electron field' etc... Oscillations are the particle wave functions

Higgs field has minimum energy when field is non-zero

Usually fields have zero energy when field is zero: energy \propto field^2

At the Big Bang: field = zero As universe cooled Higgs field 'collapsed' to minimum energy

In vacuum of empty space energy is at minimum so Higgs field is non-zero ⇒ Higgs particles are everywhere!

Any particles interacting with Higgs field acquire mass - Higgs particles slow them down

Higgs Hunting

$H \rightarrow ZZ$

 $ZZ \rightarrow IIII$ (4 lepton golden mode) $ZZ \rightarrow IIvv$ (good for high mass Higgs) $ZZ \rightarrow IIbb$ (good at high mass)

$H \rightarrow WW$

WW \rightarrow lvlv (most sensitive) WW \rightarrow lvqq (highest rate)

$H \rightarrow \chi \chi$

Rare, best for low mass Higgs high background

H→TT

Rare, good at low mass, low background

$H \rightarrow bb$

Useful but difficult to identify b quarks

Many possible Higgs decay modes/channels:

W/Z can further decay to many combinations of fermions

Each mode has different:

- sensitivity depending on mass range
- production rate
- contributions from background processes
- All modes need to be studied together!

Probability of "no Higgs" hypothesis fluctuating to mimic Higgs signal

2<u>0</u>

Transition due to the exchange of a gauge boson Exchanges momentum & quantum numbers Strength of the interaction is parameterised by couplings α One α for each fundamental force

Simplest interaction is single boson exchange

More complicated loop diagrams also contribute

Potentially infinite series of diagrams for 2 \rightarrow 2 scattering process

For each diagram calculate the transition amplitude Add all transition amplitudes Square the result to get the reaction rate

Feynman Rules: start from left side

For each vertex multiply by coupling $\sqrt{\alpha} = e$

If perturbation is small i.e. $\alpha < 1$ then contributions from extra loop diagrams is suppressed

The propagator - transfers momentum
 further a boson is from it's mass m
 the more suppressed the interaction

reaction rate / probability $\propto |M_{fi}|^2$

$$|M_{fi}|^{2} = \frac{e^{4}}{q^{4}} \frac{1}{4} \sum_{spin} \{ [\bar{u}(k')\gamma^{\mu}u(k)] [\bar{u}(k')\gamma^{\nu}u(k)]^{*} \} \{ [\bar{u}(p')\gamma_{\mu}u(p)] \{ [\bar{u}(p')\gamma_{\nu}u(p)]^{*} \} \}$$

Higgs Hunting

Supersymmetry is a particular form of string theory String theory aims to describe physics of Planck scale - domain of quantum gravity Impossible to reach in any collider!

Some quantum gravity theories live in 10 or 11 dimensional space! predict gravitons propagate in extra dimensions size of Planck length (graviton = postulated force carrier of gravity) Explains why gravity is 10²³ times weaker than Weak force - gravity is diluted

But: If extra dimensions "large" (~0.1mm) quantum gravity could be seen at TeV scale Gravity has never been tested at such short distances! LHC could open the possibility of creating mini-black holes & gravitons laboratory for testing quantum gravity!!!

11 dimensional space projected into 2d

Tragic Life of a Micro-Black Hole

Collision produces complex state as horizon forms Not all energy is trapped behind horizon

Extremely short lifetime ~ 10^{-25} s

Balding Energy lost as BH settles into 'hairless' state

Evaporation Thermal Hawking radiation in form of SM particles & gravitons Greybody factors give emission probabilities for all particles

Plank Phase For $M_{BH} \sim M_D$ unknown quantum gravity effects dominates. BH left as stable remnant or final burst of particles **????**

Tragic Life of a Micro-Black Hole

Collision produces complex state as horizon forms Not all energy is trapped behind horizon

Extremely short lifetime ~ 10^{-25} s

Balding Energy lost as BH settles into 'hairless' state

On Feb 11th 2016 the LIGO experiment announced discovery of gravitational waves

They observed two astrophysical black holes collide & merge 410 Mpc away (1 billion light years!)

Waveform of the gravity wave tells us about dynamics of the system

Ringdown is high frequency part of waveform

In this step irregularly shaped merged black hole sheds energy and stabilises

This is equivalent to 'balding phase' of a microscopic black hole

Searching for new physics is like searching for the Loch Ness Monster:

- If you observe the Loch for 24 hours and see nothing, then either:
 - a) Nessie doesn't exist
 - b) camera has poor efficiency for spotting animals (larger than 2m long)
- c) Nessie exists but comes to the surface less than once per day

Must exclude (b) and (c) before we can conclude (a) !

In searches a model predicts a reaction rate

If you observe no such reaction rate (i.e. zero collisions) then you can calculate upper limit on allowable reaction rate

Carefully consider your detector's efficiency in observing similar collisions

Do you understand background processes that mimic the signal you're looking for?

We found nothing so far...

Pile-up

- Particle trajectories from single bunch crossing 25 collisions occurred all overlapping ATLAS can reconstruct 25 separate interaction points
- Only 1 collision is interesting has much higher energy particles than other collisions
